

# Downscaling of climate projections in Japan

Meteorological Research Institute

Izuru TAKAYABU

1 Oct. 2012

01/10/2012 @Koshiba Hall

# What is downscaling?

AO-GCMs

Bridging  
between the  
global climate  
model results  
and the impact  
studies

- (1) Prepare fine scale data
- (2) Prepare the data applicable for the impact study

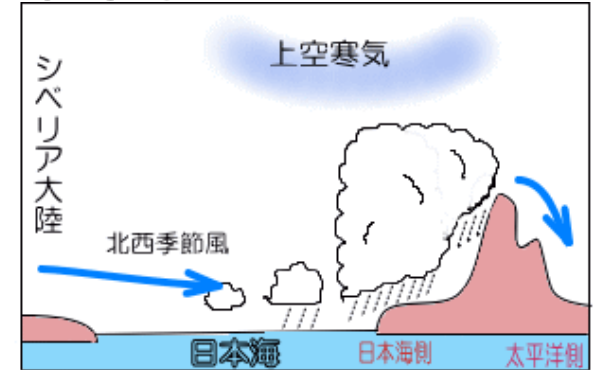

# Downscaling by using RCM

- ① Prepare fine scale data

# Local climate around Japan of winter monsoon season

**Snow depth on  
February**

(Iizuka, 2008)

(@NIED)

We need to find a critical scale for representing local climate of the specific region.

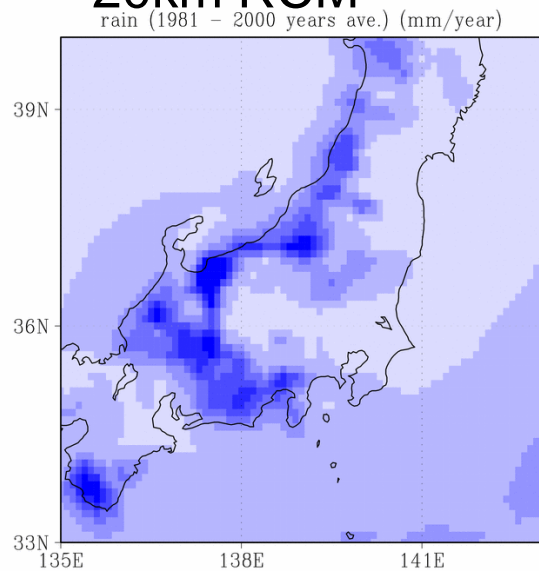

# Influence of horizontal resolution on the representation of annual total precipitation

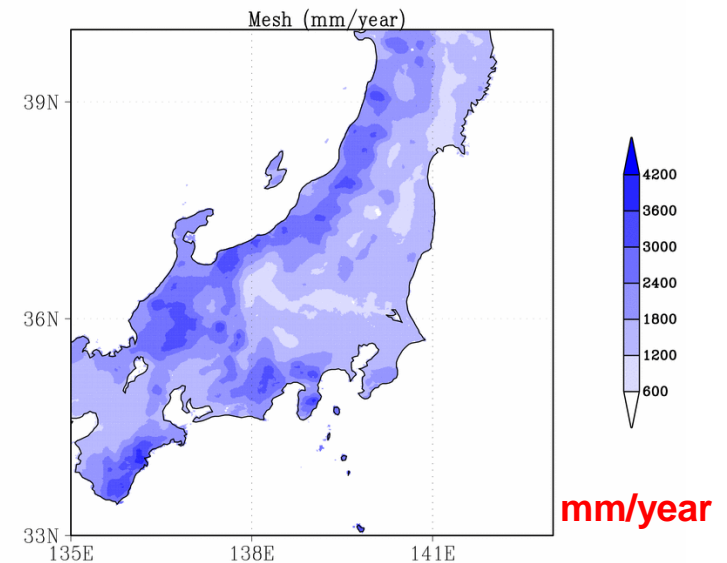

Global re-analysis data (JRA-25)  
(grid size is about 100km)

DDS by using  
20km RCM

Observation

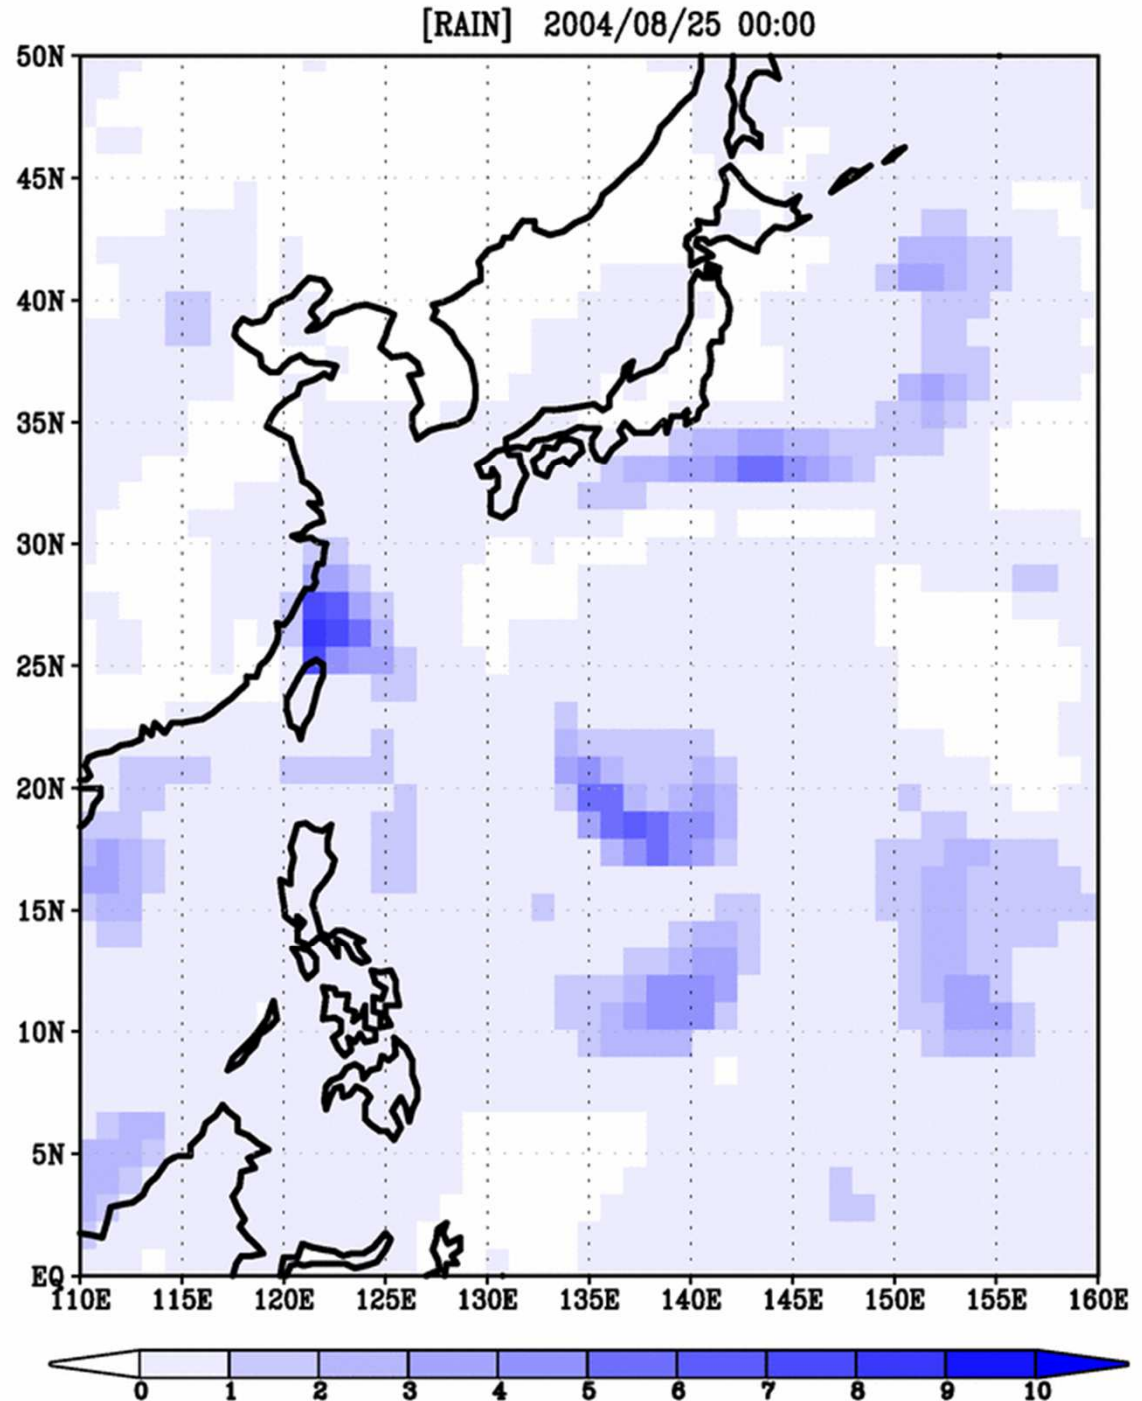

**We need at least 20km grid model to represent the local climate contrast of Japan Islands.**

Representation of meso-scale phenomena through dynamical downscaling

- \* Re-analysis data
- \* prec. mm/hr)
- \* A typhoon is approaching to Japan

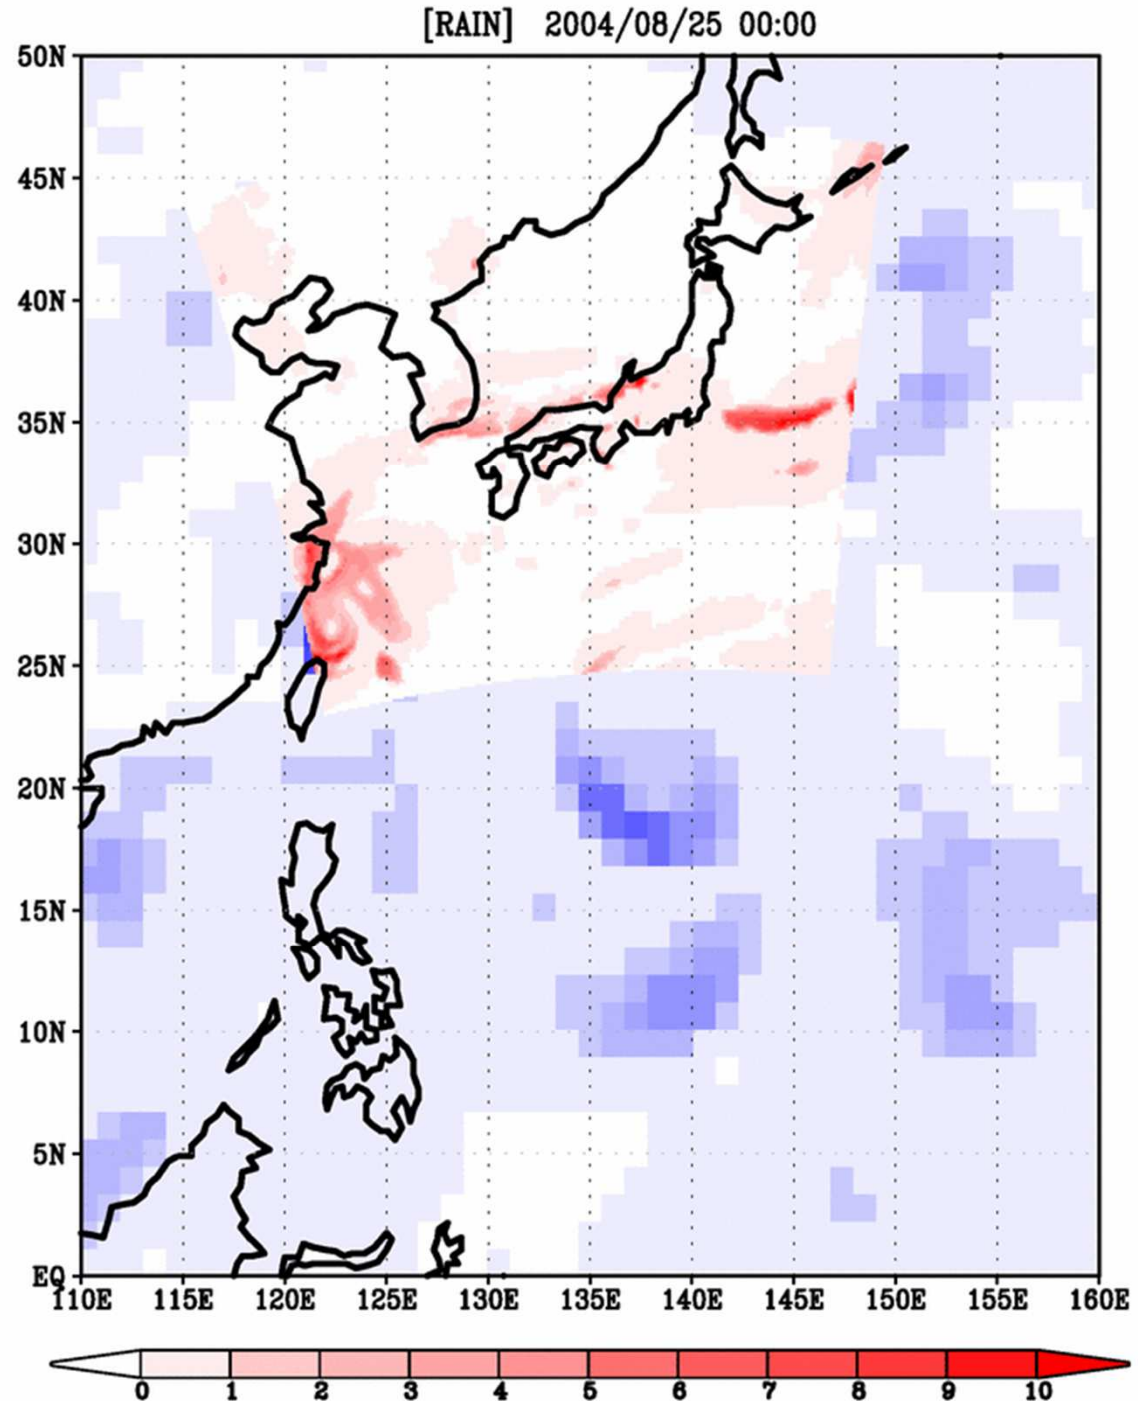

Fine mesh model has potential of representing meso-scale phenomena. This is another advantage of applying dynamical downscaling method.

Representation of meso-scale phenomena through dynamical downscaling

- \* Red area indicate the DS area
- \* rec.(mm/hr)
- \* A typhoon is approaching to Japan

Here, fine structure of a typhoon crossing the Japan Islands is represented by using dynamical downscaling method.

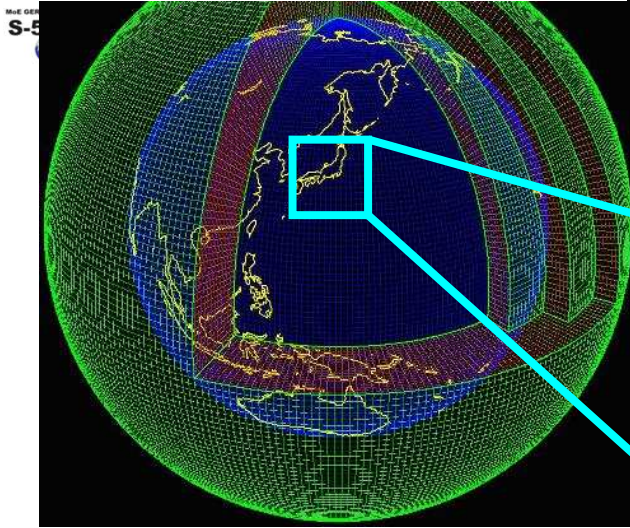

# Downscale in the urban / rural area

- ② Prepare the data applicable  
for the impact study

# Global model result

# Multi level downscaling

We nested the fine scale model into a coarse mesh model if we want to see much more fine scale !

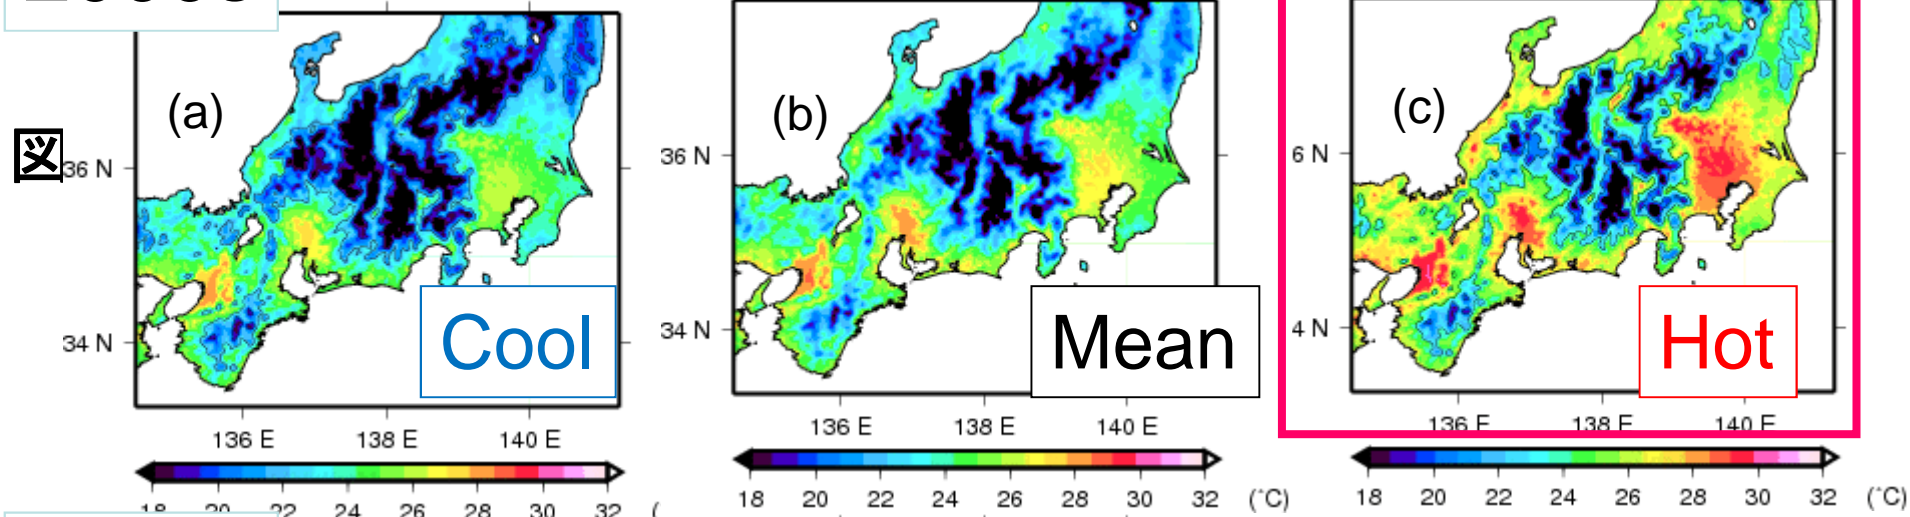

© This method is valuable for downscale the urban climate

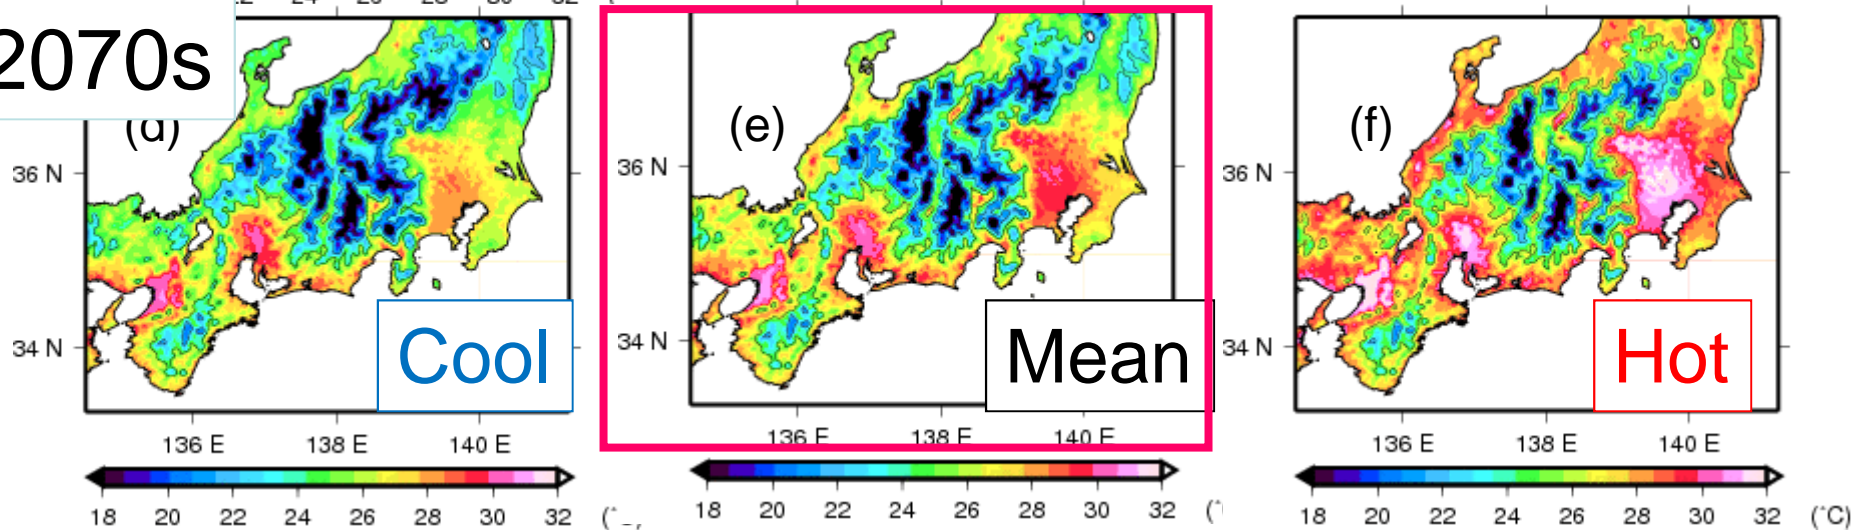

# Cool · Mean · Hot Summer in the model

2000s

2070s

The mean value of the 2070s is about the same with the hottest year in 2000s

# How to apply these data ?

- The impact studies of
  - Heat disease
  - Infectious disease
  - Food poisoning

etc.

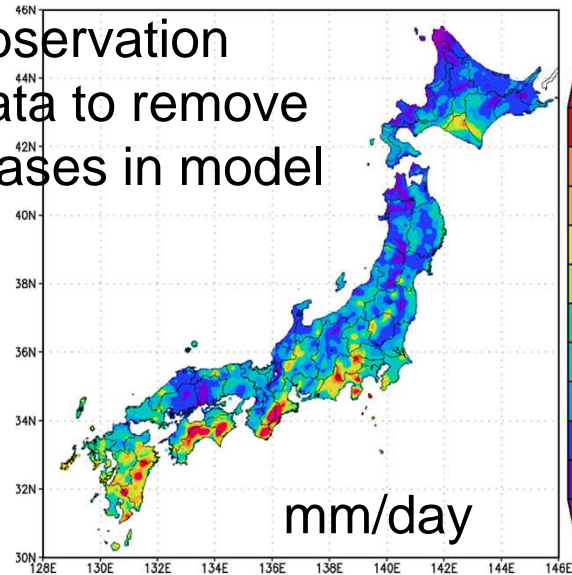

around the urban area

# Extreme rainfall amount (return period 100 years)

APHRO-JP  
(Present value)

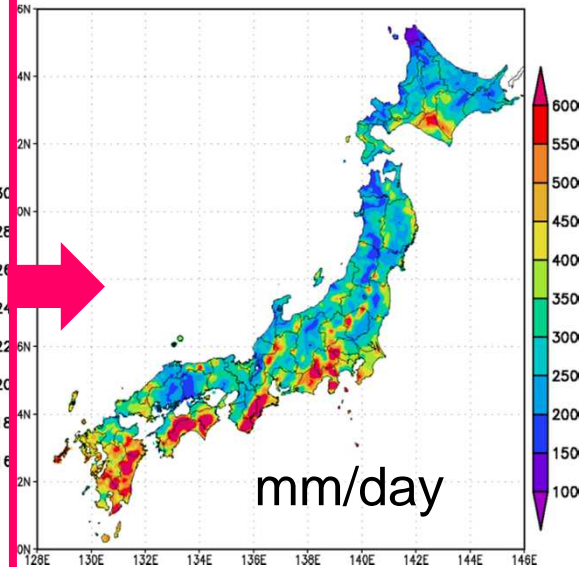

Use  
observation  
data to remove  
biases in model

Change of ratio in  
60km AGCMs data

Future projection

Take average over 10 grids by  
10grids to get enough accuracy

(Kamiguchi, 2012)

What we need to do when we apply the DS data for the impact study are . . .

- To remove biases as will be done in SDS.
- To handle the extreme value with the coarser resolution.
- To handle the data statistically only, not to handle them as a case study.

# Conclusion

Downscaling project aims to bridge between the projection results and the impact studies

For this purpose, we have done the following two things

- ① **Prepare fine scale data**
- ② **Prepare the data applicable for the impact study**

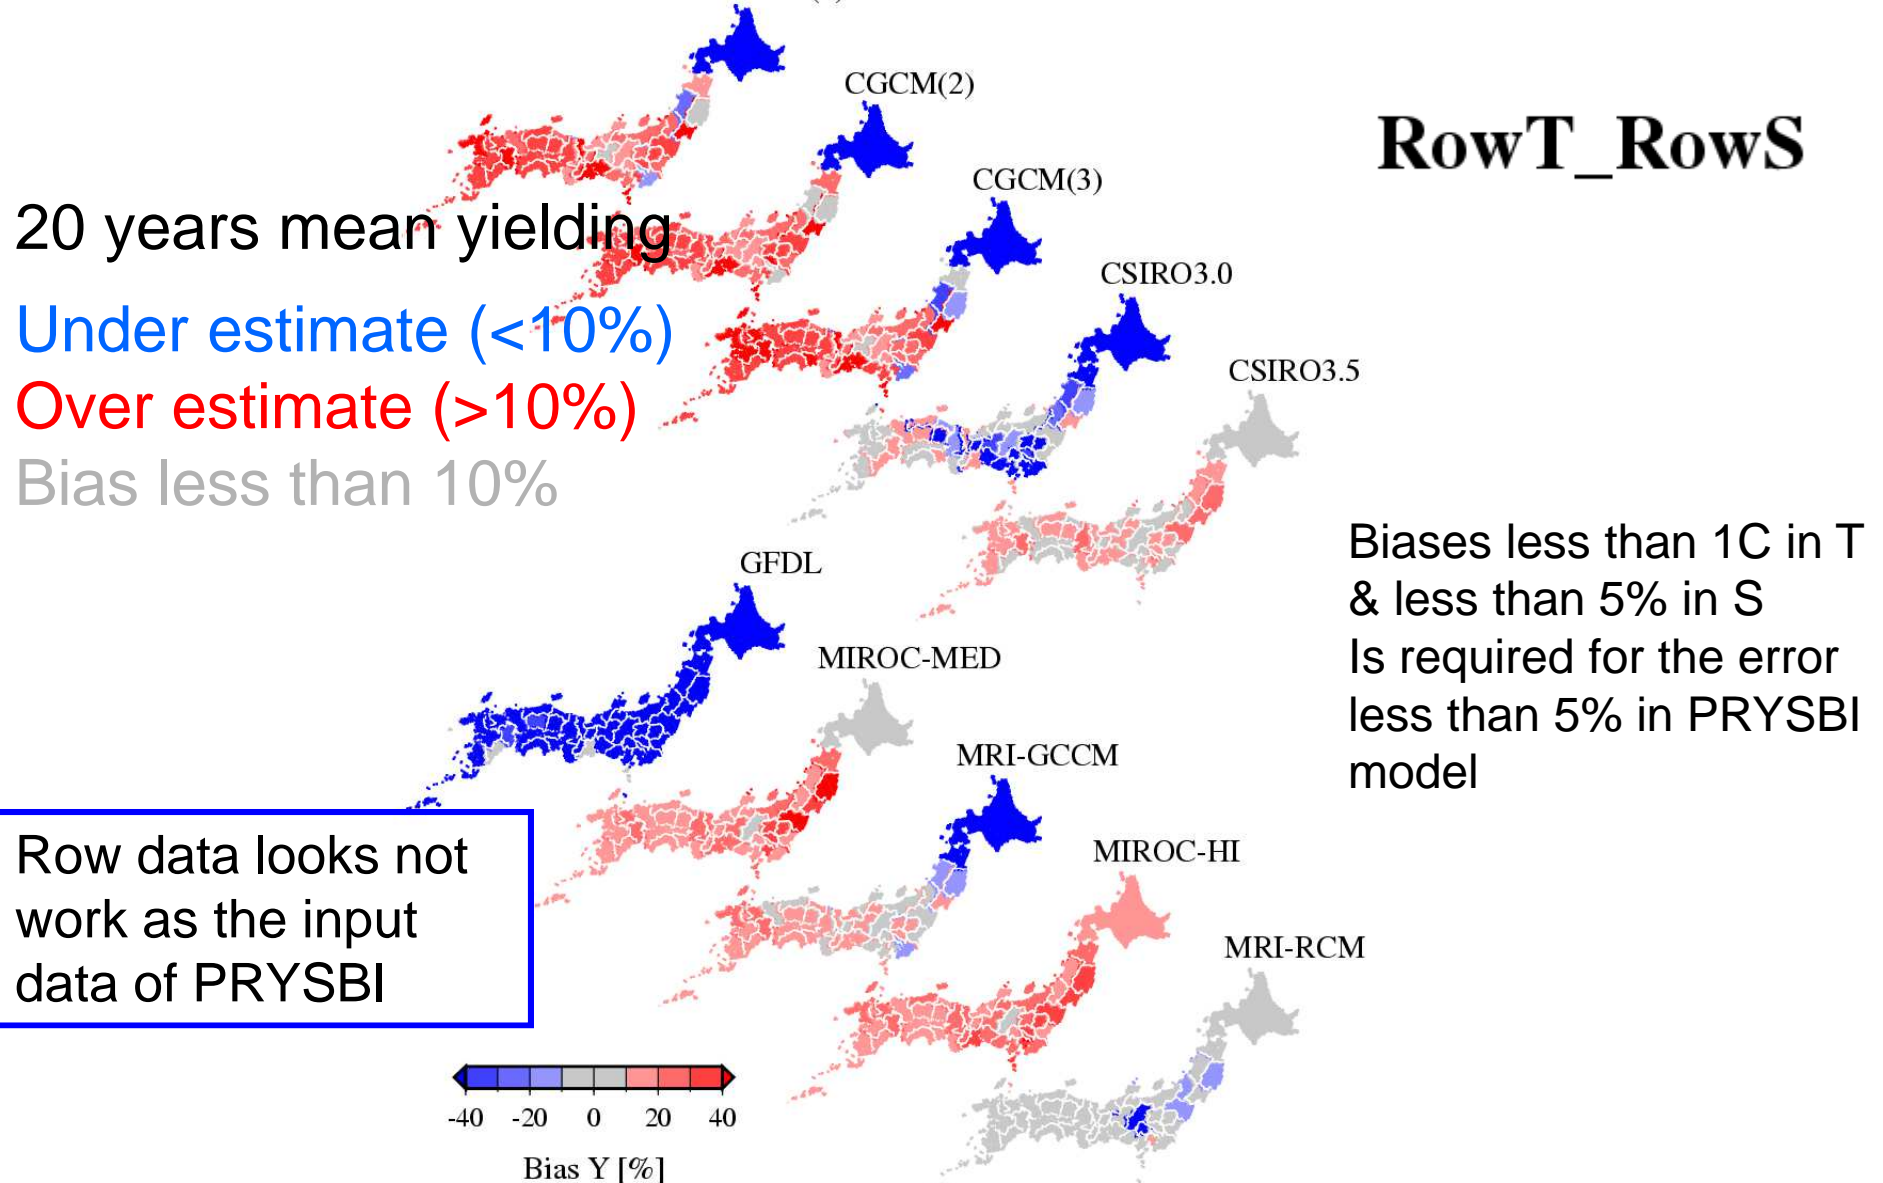

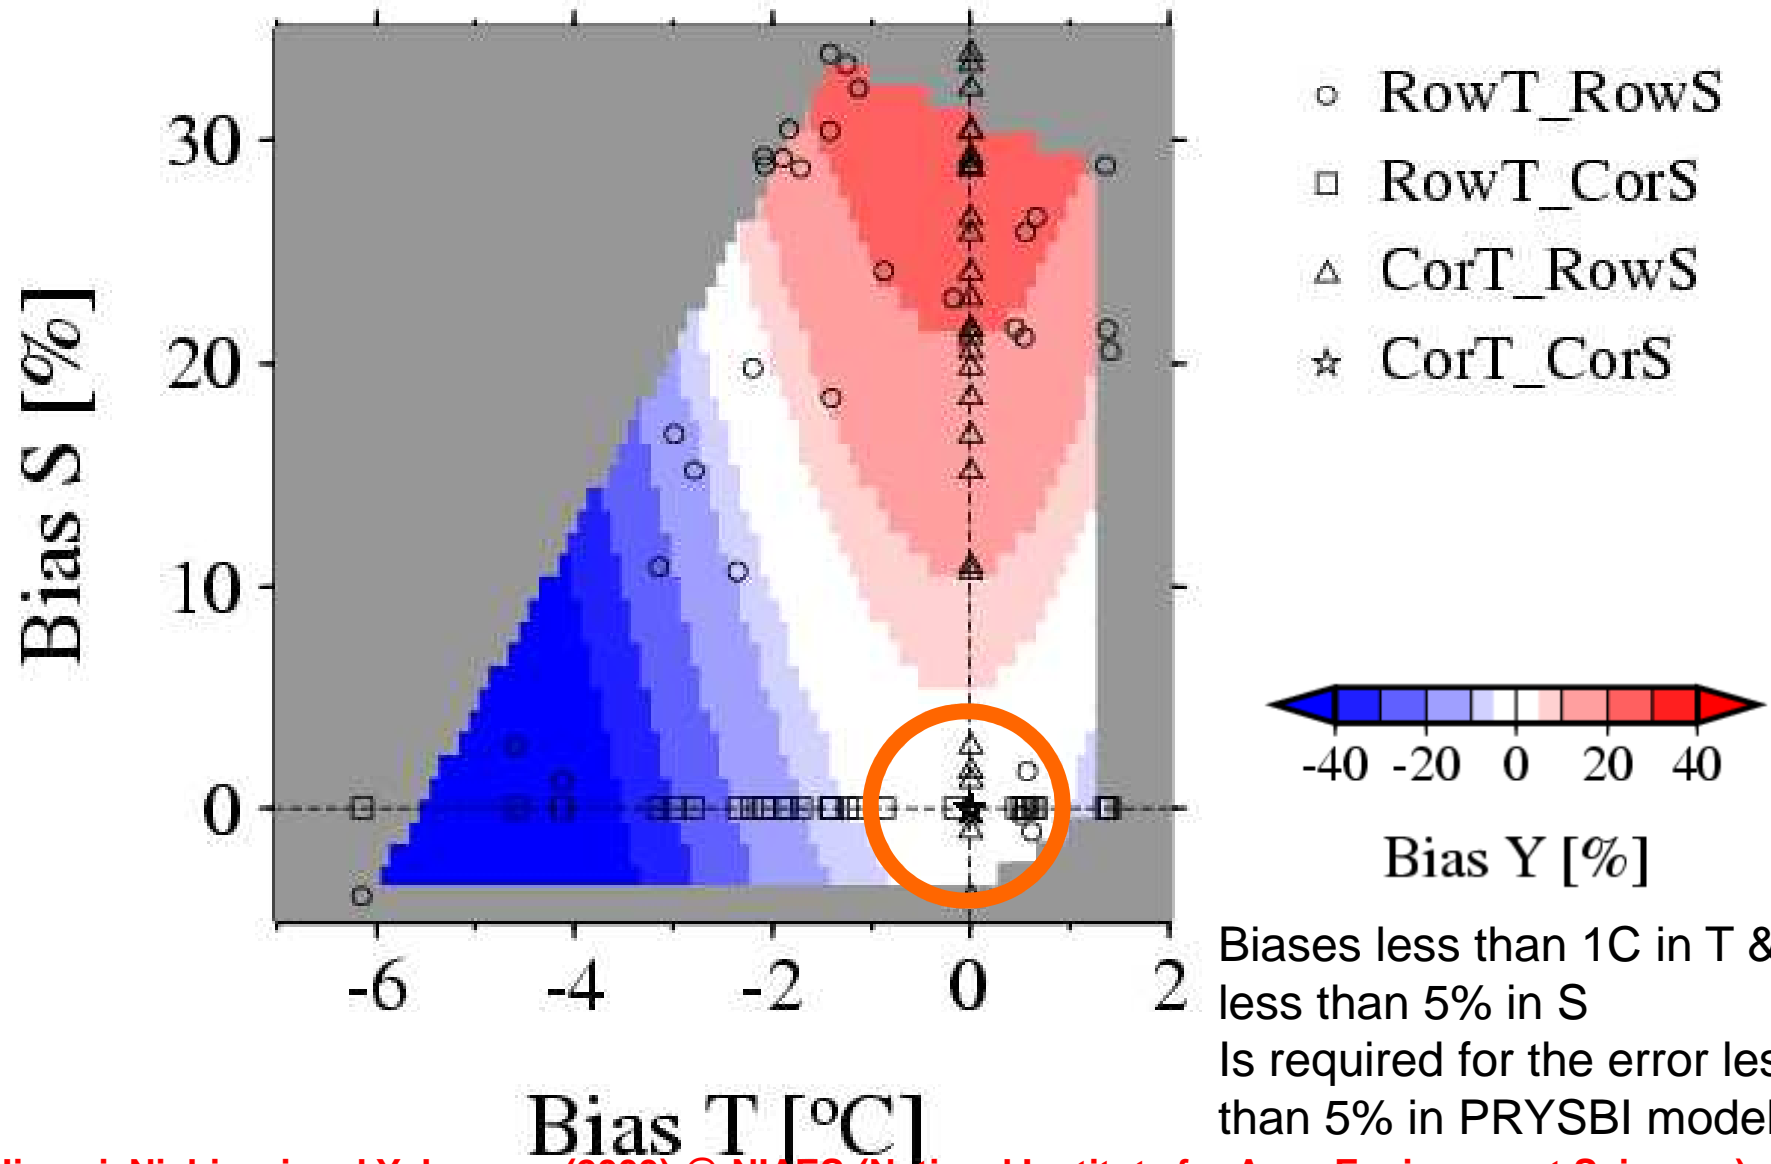

# Needs of correct bias, to use the data for crop yielding model (PRYSBI).

Needs of correct bias, to use the data for crop yielding model (PRYSBI).

# Hybrid system using DDS and SDS

- In some cases, it is more reliable to apply SDS rather than DDS (Dynamical Down Scaling). In such cases, we have to think of the parallel, or the hybrid system of DS.
- To do SDS (Statistical Down Scaling), we need the observation data of the strict point.
